Polyanion-type compounds are among the most promising electrode materials for Na-ion batteries due to their stability, safety, and suitable operating voltages. The most representative polyanion-type electrode materials are Na<sub>3</sub>V<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> and NaTi<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> for Na-based cathode and anode materials, respectively.

How do electrode materials affect the electrochemical performance of a sodium-ion battery?

The structure and functionality of electrode materials are crucial to the electrochemical performance of the sodium-ion battery. Studies have shown that cathode materials give active sodium ions and high electric potential redox potentials.

What are rechargeable sodium-ion batteries?

Rechargeable sodium-ion batteries consist of two different sodium insertion materials similar to Li-ion batteries. Sodium insertion materials, especially layered oxides, have been studied since the early 1980s, but not extensively for energy storage devices due to the expanded interest in lithium insertion materials in the 1990s.

SIBs are known as “rocking chair batteries” because sodium ions swing back and forth, similar to a rocking chair, between the positive and negative electrodes. During the charging process, sodium ions are deintercalated from the positive electrode, pass through the electrolyte and separator, and eventually embed themselves in the negative electrode.

1. Introduction. Rechargeable batteries for renewable energy storage should be made from abundant, inexpensive, and low-toxicity elements. The production of lithium-ion batteries could be limited mainly due to the scarcity of mineral reserves and the high cost of lithium and other elements such as cobalt, nickel, and copper (Figure 1) [1,2]. Therefore, ...
