

What if the internal resistance of a battery cell is not provided?

If the internal resistance of the battery cell is not provided by the manufacturer, as we'll see in this article, using the discharge characteristics of the battery cell, we can calculate the internal resistance of the battery cell, for a specific state of charge value.

What does internal resistance mean in a battery?

Internal resistance can be thought of as a measure of the "quality" of a battery cell. A low internal resistance indicates that the battery cell is able to deliver a large current with minimal voltage drop, while a high internal resistance indicates that the battery cell is less able to deliver a large current and experiences a larger voltage drop.

How to calculate the internal resistance of a battery cell?

We aim to calculate the internal resistance of the cell at approximately 47 % state of charge (SoC). Step 1. Calculate the discharge capacity of the battery cell for 47 % SoC. Since the nominal capacity of the battery cell is 3200 mA, which corresponds to 100% SoC, at 47% SoC, the battery cell capacity would be:  $0.47 \times 3200 = 1504 \text{ mAh} \approx 1500 \text{ mAh}$

What is the maximum interval on internal resistance caused by modifying discharge rate?

The maximum interval on internal resistance caused by modifying the discharge rate (0.5C-3C) is around 9 mΩ. The values of internal resistance change small (almost stable) while the discharge rate alters at the high temperature (45 °C) and the same SOC.

How many charging piles are there?

The demand for slow charging piles is only 18. Its total number is 30. There is a reduction of 80% compared with the 153 charging piles obtained from the charging demand forecast. Assume that the time cost of electric vehicles to queue or transfer to a new charging station is the same as the time cost of fuel vehicles.

What is the relationship between charging internal resistance and discharging internal resistance?

Doh et al. (2019) used intermittent current transient technology to obtain the internal resistance at different temperatures and SOC, and he established a sixth-order polynomial function relationship between charging internal resistance and discharging internal resistance at temperatures of 298K, 313K and 328K with SOC as independent variables.
