What is a phase-shifting transformer?

Phase-shifting transformers, also known as tap-changing transformers, are mechanical-based technologies that shift the phase angle of an electrical power system. Along with switched shunt capacitors and inductors, and voltage regulators, they provide a coarse level of control.

What happens if a substation does not have a capacitor?

Without capacitors, load circuits will operate at reduced voltage, motors will run slower and overheat, lights will not burn as bright, relays in process industries will drop out, etc., creating end-user system disturbances. Capacitors extend the range of substations by allowing feeder circuits to have longer runs of cable.

Why are shunt capacitors used in EHV substations?

Usually extra-high voltage (EHV) lines are used to transmit bulk power from remote generations to load centers. These long lines tend to produce significant voltage drops during peak loads. Therefore, shunt capacitors are used at the EHV substations to provide reactive power. Sometimes these capacitor banks are switched as and when required.

What is a distribution capacitor?

Distribution capacitors are installed close to the load, on the poles, or at the substations. Although these capacitor units provide reactive power support to local load, they may not help reduce the feeder and transformer losses. Low voltage capacitor units are cheaper than high voltage capacitor banks.

What are power factor correction capacitors?

These type of capacitors are probably the most visible and widely spotted by people. In the distribution systems, the power factor correction capacitors are usually installed on the poles. These installations are similar to the pole-mounted distribution transformers. The interconnections are made using insulated power cables.

Where are power factor correction capacitors installed?

In the distribution systems, the power factor correction capacitors are usually installed on the poles. These installations are similar to the pole-mounted distribution transformers. The interconnections are made using insulated power cables. Pole-mounted capacitor banks can be fixed units or switched units to meet the varying load conditions.

Three-phase reactors are manufactured for system voltages up to 400 kV. At higher voltages, the reactors usually are of single-phase type and more or less necessary for ...

the phase-shifting transformer can be represented:  $U_{k1} U_{311p} = ? p()^{1,3} pq, (9)$  where  $k p(1,3)$  - winding ratio of  $W_{1p}$  and  $W_{3p}$ . The results obtained also make it possible to express the ...
