

What is the ambient temperature of a self-healing capacitor?

The ambient temperature is set to 55 °C, and the applied voltage is ac 400 V. The temperature distributions of the shell and core of the self-healing capacitor are obtained. The results reveal that the temperature of the core is 2 °C-3 °C higher than that of the shell.

On the basis of reasonable simplifications and assumptions for capacitor structure, a 3-D temperature field numerical simulation model for a self-healing power capacitor is formulated in Fluent 15.0. The ambient temperature is set to 55 °C, and the applied voltage is ac 400 V.

How does thermal aging affect the life of polymeric film capacitors?

Thermal aging is one of the main failure mechanisms in polymeric film capacitors. In the range of 40-65 °C, experimental data in [1] shows that the lifetime of MPPFC is decreased by a factor of 2 for every 8 °C of temperature rise.

Does interlayer pressure affect the self-healing characteristics of metallized film capacitors?

Since the metallized film capacitor is a winding structure, the interlayer pressure has a certain influence on the self-healing characteristics of the metallized dielectric films. Chen pointed out that the capacitance loss of the winding MFC mainly occurs in the outer layer, and the pressure range in this area is <0.23 MPa.

What causes Selfhealing failures in metallised film capacitors?

Xun Wang explored the mechanisms of self-healing failures and discovered that the main reason for self-healing failures in metallised film capacitors is delamination of the metal layer and cracks in the metallised film resulting from excessive breakdown current.

Why do metallized polypropylene film capacitors fail under different temperature and voltage?

The lifetime of MPPFC under different temperature and voltage is tested. Reason of the increase of self-healing area with temperature rise is analyzed. Reason of the occurrence of higher catastrophic failure ratio is analyzed. Thermal aging is one of the main failure mechanisms in metallized polypropylene film capacitors (MPPFCs).

This paper deals with the effect on aging acceleration due to harmonics for a simple insulation system, i.e. low-voltage self-healing capacitors. The most stressing features of the nonsinusoidal voltage and current waveforms (peak value, rms value, slope, etc.), as well as temperature, are investigated in order to single out the extent of their effect on life reduction.

This phenomenon is termed as "self-healing" [5]. The self-healing or clearing process in metallized film capacitors depends on three factors, namely, the working voltage, mechanical pressure between the winding layers, and metallization thickness (resistivity) [6]. Accumulation of these self-healing events over time, causes a "soft"
