

Simple voltage stabilization for solar cells

What is a solar cell in a photovoltaic system?

The solar cell is the basic component of a photovoltaic (PV) system. The cells are formed in parallel or series to produce the necessary current, voltage, and high power that forms a PV array. Each solar cell has a p-n junction of semiconductor materials, similar to a diode.

How stable are perovskite solar cells?

The intrinsic stability of the perovskite layer and key interfaces remains the primary challenge in the commercialization of perovskite solar cells (PSCs), despite the significant advancements in laboratory-scale PSCs, achieving certified power conversion efficiency (PCE) over 26% [4].

Can perovskite solar cells be commercialized?

The primary challenge in commercializing perovskite solar cells stems from the fragile and moisture-sensitive nature of perovskite materials. Here, authors propose a multi-functional asynchronous cross-linking strategy and achieve high-performance and stable devices with mere 0.30 voltage deficit.

What is the power conversion efficiency of perovskite solar cells?

The power conversion efficiency (PCE) of perovskite solar cells (PSCs) have soared to a certified value of 25.5% in recent years, [1] exceeding that of the commercialized rivals, such as polycrystalline silicon, cadmium telluride, copper indium gallium (di)selenide CIGS, and CdTe thin-film solar cells.

What temperature should a solar cell operate in?

Solar cells are expected to operate under a wide range of climates, with temperatures ranging from about -20 to 70 °C, within which the tetragonal or cubic perovskite structure should be retained.

How a microgrid is able to maintain a stable voltage and frequency?

To preserve a stable voltage and frequency of a microgrid comprising solar, wind, FC, battery and load, a robust Iterative Learning Controller (ILC) works under autonomous and grid-connected modes with variable generation and loading conditions (Angalaeswari and Jamuna, 2020).
