

What are solar cells & photodetectors?

Solar cells and photodetectors are devices that convert an optical input into current. A solar cell is an example of a photovoltaic device, i.e., a device that generates voltage when exposed to light.

What is a short circuit current in a solar cell?

The short-circuit current (ISC) is the current through the solar cell when the voltage across the solar cell is zero (i.e., when the solar cell is short circuited). Usually written as ISC, the short-circuit current is shown on the IV curve below. ISC is due to the generation and collection of light-generated carriers.

How do solar cells work?

Solar cells are semiconductor-based devices primarily, which convert sunlight directly to electrical energy through the photovoltaic effect, which is the appearance of a voltage and current when light is incident on a material.

What causes a dark current in a PN junction device?

The dark current in a pn junction device then arises from recombination currents due to this excess carrier, both in the bulk of the n- and p-regions through diffusion outside the SCR, as well as recombination within the SCR.

What factors affect solar cell recombination?

We then go into detail of the basics of solar cell operation, and the effects of various factors on the primary figures of merit, the open circuit voltage, short circuit current, and fill factor. In particular we focus on recombination, both in terms of the photocurrent and the dark current affecting the cell voltage.

What does ISC mean in solar cells?

The short-circuit current (I_{SC}) is the current through the solar cell when the voltage across the solar cell is zero (i.e., when the solar cell is short circuited). Usually written as ISC, the short-circuit current is shown on the IV curve below. I is due to the generation and collection of light-generated carriers. For an ideal PV cell with

7 Choice of photodiode materials A photodiode material should be chosen with a bandgap energy slightly less than the photon energy corresponding to the longest operating wavelength of the system. This gives a sufficiently high absorption coefficient to ensure a good response, and yet limits the number of thermally generated carriers in order to attain a low "dark current" (i.e.
